

# Neural Network Solvers for Combinatorial Optimization

---

## Graph 9. Auto-regressive CO Solvers

---

1

## Outline of 3 Lectures: Graph 9, 10 and 11

---

- Introduction to ML for Combinatorial Optimization (CO)
- Autoregressive (AR) CO Solvers
- Non-autoregressive (NAR) CO Solvers
- Pre-trained Large Language Models [C Yang et al., **ICLR 2024**]

2

## Combinatorial Optimization (CO)

**Combinatorial Optimization (CO)** is a subfield of **mathematical optimization** that consists of finding an optimal object from a **finite set** of objects,<sup>[1]</sup> where the set of **feasible solutions** is **discrete** or can be reduced to a discrete set.

Traveling Salesmen Problem (TSP)

Maximal Independent Set (MIS)

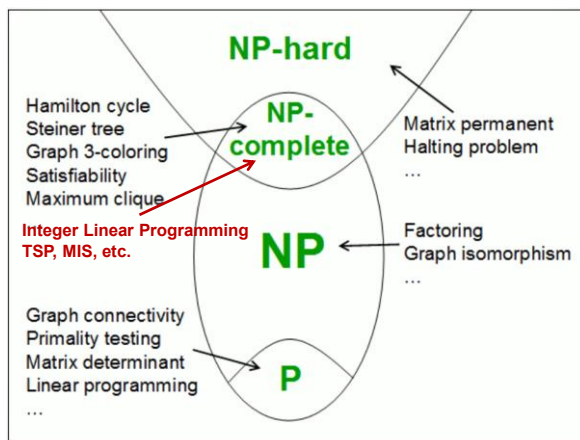

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

3

3

## P, NP and NP Complete (NPC)

- **P**: The class of problems which can be solved by algorithms in polynomial time..
- **NP**: The class of problems for which a deterministic way to find a solution in polynomial time is not known; however, a guessed solution can be verified in polynomial time.
- **NP Complete (NPC)**: If a problem is in NP and all other NP problems can be reduced to it in polynomial time, the problem is NP-complete.
- **We want:**  $NPC \xrightarrow{\text{approximate}} P$

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

4

4

## TSP vs. MIS: What do they have in common?

Traveling Salesmen Problem (TSP)

Maximal Independent Set (MIS)

- Both can be defined as a **search problem over a graph** (for an optimal solution).
- A candidate solution can be generated by **sequentially selecting a variable** (node or edge) in each step under certain constraints.
- This process reminds us about **Language Modeling** for generating a word sequence.
- So, can we use Transformer or ChartGPT to solve CO problems and beat existing methods?**

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

5

5

## TSP Solvers

### Traditional Algorithms

- Exhaustive search:  $O(n!)$
- Dynamic Programming:  $O(n^2 2^n)$
- Linear Programming: scaled to graphs with  $n = 200$  nodes
- Heuristic and approximate solvers: heavily depend on hand-craft heuristics

### Neural Network Solvers (Recent ML models)

-  **DRL** (deep reinforcement learning) solvers proposed recently (ICLR 2017, ICLR 2019), scaled to  **$n = 100$  nodes until 2022**
-  **DIMES** (our DRL model): scaled  **$n = 10,000$  nodes** (R Qui, Z Sun & Y Yang, NearIPS'2022)
-  **DIFUSCO** (our graph-based diffusion model): **outperforming DIMES** both in scalability and accuracy (Z Sun and Y Yang, ICML 2023)

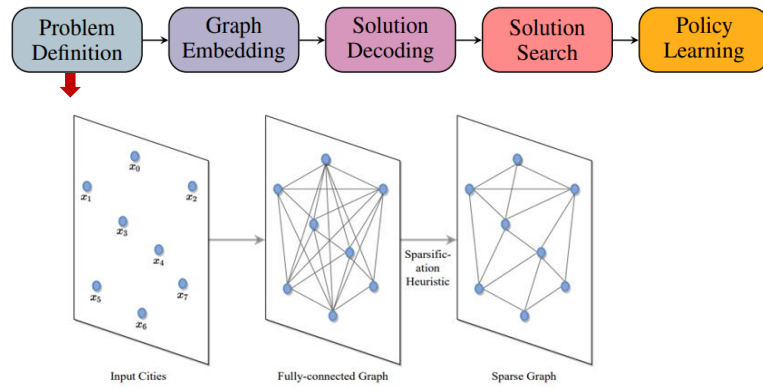

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

6

6

## Neural CO Pipeline [CK Joshi et al, CP 2021]

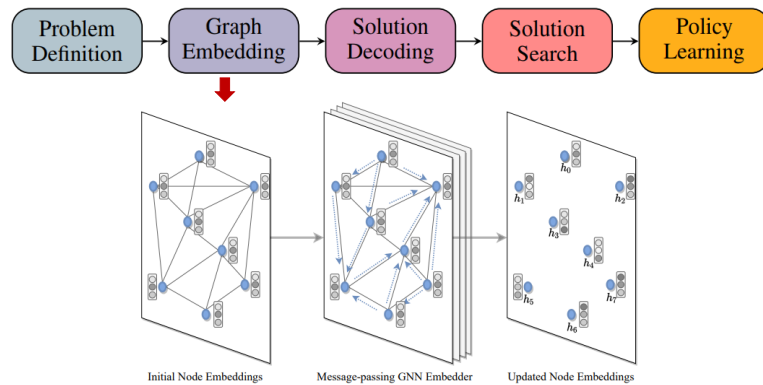

(b) **Problem Definition:** TSP is formulated via a fully-connected graph of cities/nodes. The graph can be sparsified via heuristics such as  $k$ -nearest neighbors.

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

7

## Neural CO Pipeline

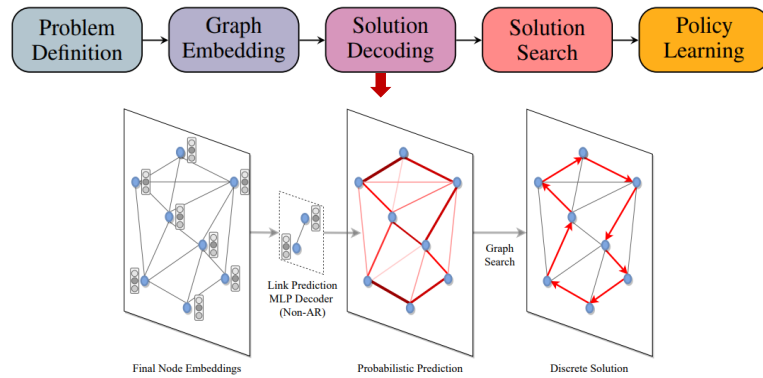

(c) **Graph Embedding:** Embeddings for each graph node are obtained using a Graph Neural Network encoder, which builds local structural features.

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

8

## Neural CO Pipeline

3/28/2024

(d) **Solution Decoding & Search:** Probabilities are assigned to each node for belonging to the solution set, either independent of one-another (*i.e.* Non-autoregressive decoding) or conditionally through graph traversal (*i.e.* Autoregressive decoding). The predicted probabilities are converted into discrete decisions through classical graph search techniques such as greedy search or beam search.

9

9

## Decoding Strategies

### Autoregressive (AR) Solvers

Encoder-Decoder Neural Networks

### Non-autoregressive (NAR) Solvers

Encoder + Active Search (not Trinet)

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

10

10

## Neural CO Pipeline

### 3.4 Solution Search

**Greedy Search** For AR decoding, the predicted probabilities at node  $i$  are used to select the edge to travel along at the current step via sampling from the probability distribution  $p_i$  or greedily selecting the most probable edge  $p_{ij}$ , i.e. greedy search. Since NAR decoders directly output probabilities over all edges independent of one-another, we can obtain valid TSP tours using greedy search to traverse the graph starting from a random node and masking previously visited nodes. Thus, the probability of a partial tour  $\pi'$  can be formulated as  $p(\pi') = \prod_{j' \sim i' \in \pi'} p_{i'j'}$ , where each node  $j'$  follows node  $i'$ .

**Beam Search and Sampling** During inference, we can increase the capacity of greedy search via limited width breadth-first beam search, which maintains the  $b$  most probable tours during decoding. Similarly, we can sample  $b$  solutions from the learnt policy and select the shortest tour among them. Naturally, searching longer, with more sophisticated techniques, or sampling more solutions allows trading off run time for solution quality. However, it has been noted that using large  $b$  for search/sampling or local search during inference may overshadow an architecture's inability to generalize [20]. To better understand generalization, we focus on using greedy search and beam search/sampling with small  $b = 128$ .

11

11

## Neural CO Pipeline

### Supervised Learning from Labeled Training Data

- $\mathcal{D} = \{(s_i, \pi_i)\}$  for  $s_i$  as an instance graph and  $\pi_i$  as a ground-truth optimal solution for  $s_i$ .
- Train a GNN AR model (RNN or Transformer based) or an MLP classifier over  $\mathcal{D}$ .

### Unsupervised Reinforcement Learning from a Cost Function

- 1)  $S = \{s_i\}$  is a large set of graphs without ground-truth optimal solution per graph.
- 2) For each  $s \in S$ , generate feasible solutions ( $\pi'$ 's) based on the current heatmap  $P_\theta(\pi|s)$ .
- 3) Evaluate each feasible solution with a cost function, producing  $cost(\pi_1), cost(\pi_2), cost(\pi_3), \dots$ ;
- 4) Use the costs of the explored solutions to update the heatmap with policy gradient;
- 5) Repeat steps 2-4 for a prespecified number of iterations.

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

12

12

## AR decoding v.s. NAR decoding

Figure 7: **Comparing AR and NAR decoders.** Sequential AR decoding is a powerful inductive bias for TSP as it enables significantly better generalization, even in the absence of graph structure (MLP encoders).

Figure 8: **Inference time for various decoders.** One-shot NAR decoding is significantly faster than sequential AR, especially when re-embedding the graph at each decoding step [39].

## Autoregressive Factorization in Decoding

Denoting  $x = (x_1, x_2, \dots, x_S)$  and  $y = (y_1, y_2, \dots, y_T)$ , we have

$$P_\theta(y|x) = \prod_{j=1}^T P_\theta(y_j | x, y_{<j}) = \prod_{j=1}^T P_\theta(y_j | h_{j-1}) = \frac{\exp(y_j^T h_{j-1})}{\sum_{j'=1}^M \exp(y_{j'}^T h_{j-1})}$$

where  $h_{j-1}$  encodes the information of  $x, y_{<j}$ .

*remember this rule:*

$$P(X, Y | Z) = P(X | Y, Z)P(Y | Z)$$

## Notation

- $s \in D$  is an instance graph in collection  $D$ .
- $\pi = (\pi_1, \pi_2, \dots, \pi_n)$  is a **feasible solution** (valid TSP tour) in  $s$ , and  $\pi_i$  is an edge in the tour.
- $c_s(\pi_i)$  is the (non-negative) cost of edge  $\pi_i$  and  $\mathcal{L}(\pi) = \sum_{i=1}^n c_s(\pi_i)$  is the total cost of  $\pi$ .
- $p_\theta(\pi|s)$  is the probabilistic distribution learnable by a neural network
  - Ideally, we want  $p_\theta(\pi^*|s) = 1$  for any optimal solution and  $p_\theta(\pi|s) = 0$  otherwise.
  - Practically, we train a transformer model which assigns high  $p_\theta(\pi|s)$  values to near-optimal solutions.
- AR factorization:  $p_\theta(\pi|s) = \prod_{i=1}^n p_\theta(\pi_i | \pi_{<i}, s) = \prod_{i=1}^n P_\theta(\pi_i | h_{i-1})$

3/28/2024

20

20

Rule  $\rightarrow \nabla f(x) = f(x) \nabla \log(f(x))$

## Optimization

- Expected loss

$$\mathcal{L}_\theta(s) = E_{\pi \sim p_\theta(\cdot|s)}[\mathcal{L}(\pi|s)] = \sum_{\pi|s} [\mathcal{L}(\pi|s) p_\theta(\pi|s)] \quad (1)$$

- Gradient for optimizing

$$\nabla_\theta \mathcal{L}_\theta(s) = E_{\pi \sim p_\theta(\cdot|s)}[\mathcal{L}(\pi) \nabla_\theta \log p_\theta(\pi|s)] \quad (2)$$

- To proof formula 2, let us use the trick below (omitting  $s$  for simplicity)

$$\nabla_\theta p_\theta(\pi) = p_\theta(\pi) \frac{\nabla_\theta p_\theta(\pi)}{p_\theta(\pi)} = p_\theta(\pi) \nabla_\theta \log p_\theta(\pi) \quad (3)$$

- On both sides of (3), multiply  $\mathcal{L}(\pi)$  and sum over  $\pi$  we have

$$\text{LHS: } \sum_{\pi} [\mathcal{L}(\pi) \nabla_\theta p_\theta(\pi)] = \nabla_\theta (\sum_{\pi} [\mathcal{L}(\pi) p_\theta(\pi)]) = \nabla_\theta \mathcal{L}_\theta(s) \quad (4)$$

$$\text{RHS: } \sum_{\pi} [\mathcal{L}(\pi) p_\theta(\pi) \nabla_\theta \log p_\theta(\pi)] = E_{\pi \sim p_\theta(\cdot)}[\mathcal{L}(\pi) \nabla_\theta \log p_\theta(\pi)] \quad (5)$$

3/28/2024

@Yiming Yang, 11-741 S24 Graph9 AR CO Solvers

21

21

## Optimization

- Gradient for minimization

$$\nabla \mathcal{L}_\theta(s) = \sum_{\pi \sim p_\theta(\cdot|s)} \mathcal{L}(\pi) \nabla \log p_\theta(\pi|s) \quad (2)$$

- Adjusted gradient

$$\nabla \mathcal{L}_\theta(s) = \sum_{\pi \sim p_\theta(\cdot|s)} [\mathcal{L}(\pi) - b_s] \nabla \log p_\theta(\pi|s)$$

- $b_s$  is the cost of the predicted tour by a baseline system (GreedyRollout), reflecting the difficulty of problem  $s$ ;

- $\mathcal{L}(\pi) - b_s$  is the **adjusted weight**, reflecting the additional cost the system-predicted  $\pi$  is compared to that by the baseline.

24

# What are the AR methods?

## Concluding Remarks

- **Bad News:** ML solvers cannot beat exact solvers for small graphs ( $n \leq 100$  nodes) because exact solvers guarantees to find optimal solutions when they can scale.
- **Good News:** ML solvers can find **near-optimal solutions** for small problems.
- **The Hope:** **Scaling up** ML solvers for large problems that cannot be solved by exact solvers and still finding high-quality solutions for the large problems.
- **Recent Progress:** Non-autoregressive (NAR) neural solvers (e.g., DIMES and Difusco) and pretrained LLMs (e.g. OPRO)
