### Consider a Vanilla Neural Network

e.g., for hand-writing digit recognition

Input layer

 $x \in \mathbb{R}^D$  is the feature vector of an image.

Hidden layer

$$\begin{split} h &= g(W_{xh}x) = \ (g(x_1), g(x_2), ..., g(x_D))) \\ g(x_i) &\stackrel{\text{def}}{=} \tanh(x_i) = \frac{e^{x_i} - e^{-x_i}}{e^{x_i} + e^{-x_i}} \quad \text{(rescaled logistic sigmoid)} \end{split}$$

Output layer

$$\hat{y} = f(\underbrace{W_{hy}h}) = (f_1(z), f_2(z), \dots, f_K(z))$$

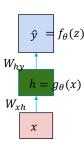

$$f_j(z) = softmax(z) = \frac{\exp(z_j)}{\sum_{j'} \exp(z_{j'})}$$

the estimated probability of category j given  $z = W_{hy}h$ 

Model Parameters  $\boldsymbol{\Theta} = (W_{xh}, W_{hy})$ 

1/23/2024

@Yiming Yang, S24 DL2 lecture on RNN

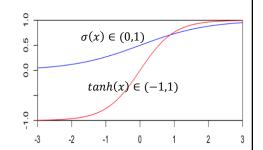

## Tanh function is a rescaled sigmoid

$$\sigma(x) \stackrel{\text{\tiny def}}{=} \frac{e^x}{1 + e^x} \qquad \qquad for \ x \in (-\infty, \infty),$$

$$\phi(x) = 2\sigma(2x) - 1$$

$$= 2\frac{e^{2x}}{1 + e^{2x}} - 1 = \frac{e^{2x}}{1 + e^{2x}} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\stackrel{\text{def}}{=} \tanh(x)$$

5

#### Limitation of the Vanilla Neural Network

- Cannot model the input as a sequence of tokens but treating the input as a vector of in variables instead.
- Cannot produce sequential output but treating the output as a set of variables (with a probability score of each).
- Cannot support language modeling, the task to sequentially predict the next word based on the previous words

7

[Adapted from F.F. Li et al. Stanford CS231n]

### Recurrent Neural Network (RNN)

• Modeling a sequence of  $(x_t, h_t, y_t)$  as

• The same  $\theta$  used at each time step

 $\theta = \{W_{xh}, W_{hy}, W_{hh}\}$ 

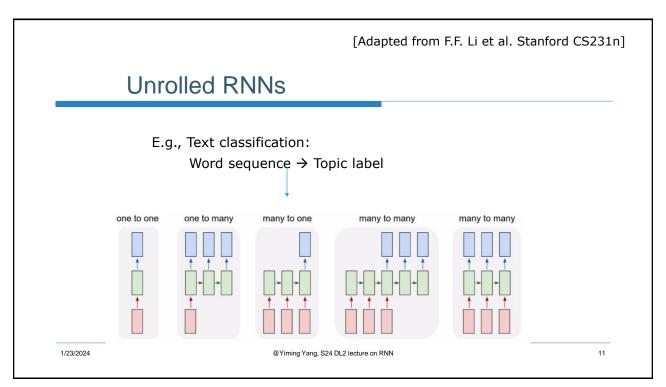

1/23/2024 @Yiming Yang, S24 DL2 lecture on RNN

 $\hat{y}_t$   $W_{hy}$   $h_t$   $W_{xh}$

### Why do gradients vanish (or explode) in neural nets?

- "Neural Networks and Deep Learning", Chapter 5, by Michael Nielsen (Dec 2017), <a href="http://neuralnetworksanddeeplearning.com/chap5.html">http://neuralnetworksanddeeplearning.com/chap5.html</a>
- Example: a multi-layer nnet with a sigmoid function at each layer
- Showing how the gradient of the output variable w.r.t. an input-layer variable would vanish or explode when the number of layers increases
- More generally, "neural networks suffer from an unstable gradient problem."

17

17

[based on the RNN tutorial by WILDML, 2015]

### Why do gradients vanish in RNN?

• We could (incorrectly) compute the gradient of loss function  $L(y,\hat{y})$  as

$$\frac{\partial L}{\partial W_{hh}} = \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_4} \frac{\partial h_4}{\partial W_{hh}}$$

• But  $h_4$  also depends on  $h_3, h_2, h_1$ , and each  $h_i$  depends on  $W_{hh}$ .

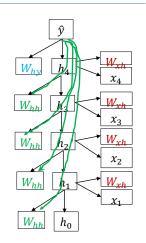

So, the correct formula should be

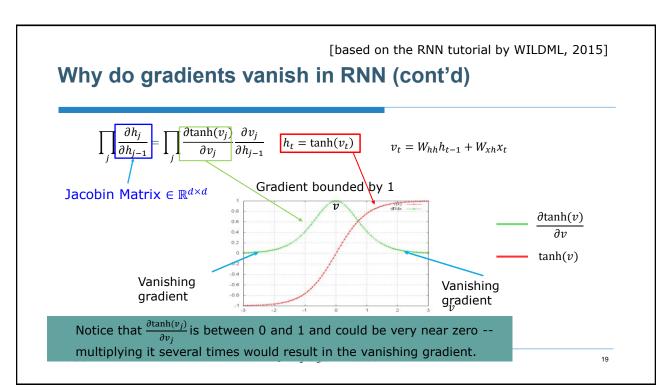

$$\begin{split} \frac{\partial L}{\partial W_{hh}} &= \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_4} \frac{\partial h_4}{\partial W_{hh}} + \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_4} \frac{\partial h_3}{\partial h_3} \frac{\partial h_3}{\partial W_{hh}} \\ &+ \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_4} \frac{\partial h_3}{\partial h_3} \frac{\partial h_3}{\partial h_2} \frac{\partial h_2}{\partial W_{hh}} + \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_4} \frac{\partial h_3}{\partial h_3} \frac{\partial h_2}{\partial h_2} \frac{\partial h_1}{\partial h_h} \\ &= \sum_{i=1}^n \frac{\partial L}{\partial \hat{y}} \frac{\partial \hat{y}}{\partial h_n} \left( \prod_{j=i+1}^n \frac{\partial h_j}{\partial h_{i-1}} \right) \frac{\partial h_i}{\partial W_{hh}} \quad \text{(here } n=4) \end{split}$$

• When n is large (e.g., 500), we have a long chain of  $\prod_j \frac{\partial h_j}{\partial h_{j-1}}$

21

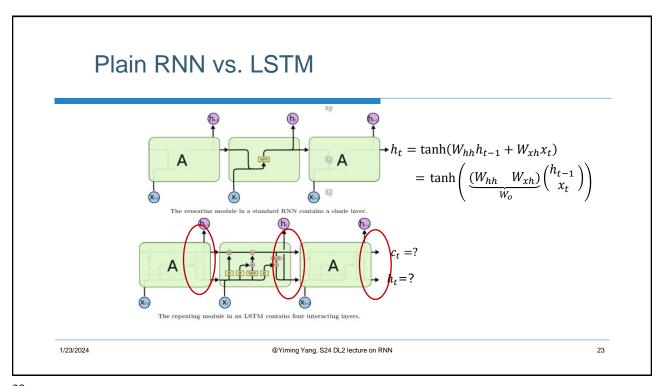

21

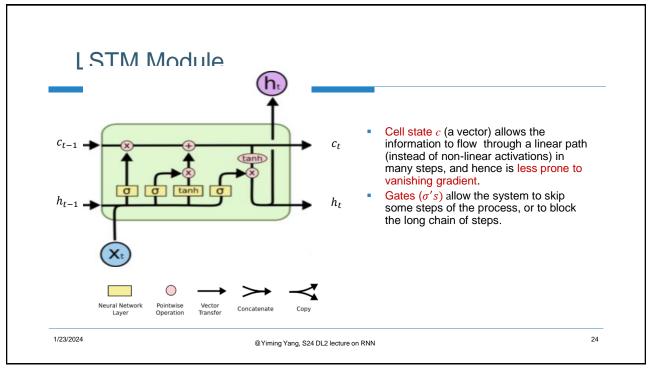

#### **Gated Recurrent Neural Networks**

- LSTM (Long Short Term Memory) as a representative model
- Introducing gates to plain RNN, to shorten the information flow and to avoid non-linear operations (like tanh) as needed
- Meditating the gradient vanishing issue in RNN effectively

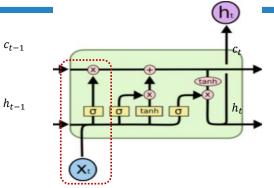

1/23/2024

@Yiming Yang, S24 DL2 lecture on RNN

#### **LSTM Module**

Forget gate  $f_t = \sigma(W_f * [h_{t-1}, x_t] + b_f)$ Input gate  $i_t = \sigma(W_i * [h_{t-1}, x_t] + b_i)$ Output gate  $o_t = \sigma(W_o * [h_{t-1}, x_t] + b_o)$ The behavior of the gates are controlled by

model parameters of W's and b's.

- $f_t = \sigma(.) \in (0,1)$  mimic a soft gate.
- $f_t \rightarrow 0$  means the gate is closed, forcing  $c_{t-1}$  (old memory) to be forgotten.
- $f_t \rightarrow 1$  means the gate is open, allowing  $c_{t-1}$  (old memory) to be kept.

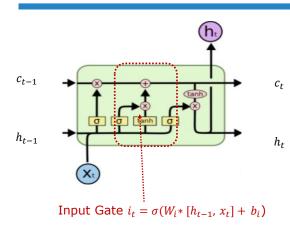

1/23/2024

@Yiming Yang, S24 DL2 lecture on RNN

2

25

### **LSTM Module**

Linear path

$$c_t = f_t * c_{t-1} + i_t * g_t$$

Non-linear function

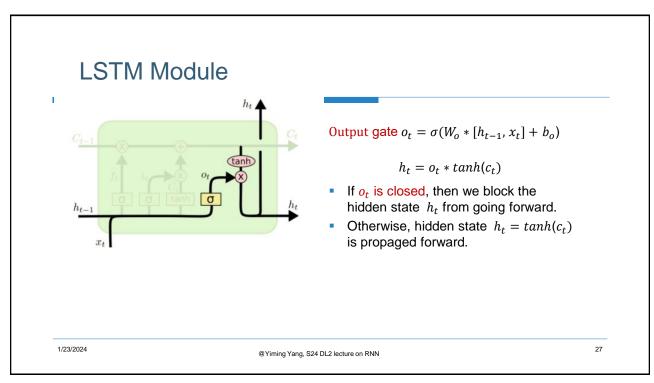

$$g_t = \tanh(W_c * [h_{t-1}, x_t] + b_c)$$

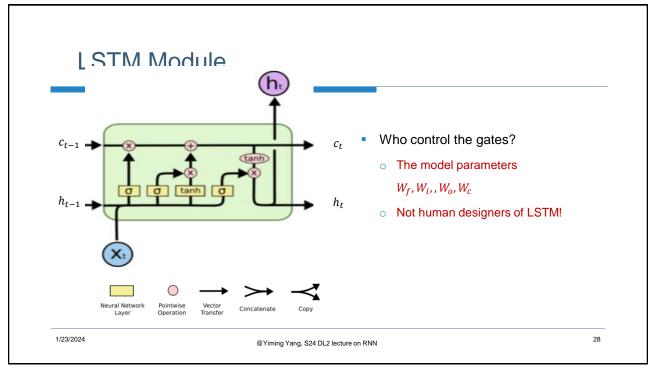

- If  $i_t$  is closed, then input  $x_t$  is skipped in the updating of  $c_t$ .
- If  $i_t$  is open but  $f_t$  is closed, then we forget  $c_{t-1}$  and renew  $c_t$  with  $g_t$

#### Performance on language modeling [Yoon Kim et al. AAAI 2016]

PPL Size LSTM-Word-Small 97.6 5 m LSTM-Char-Small 5 m LSTM-Word-Large 85.4 20 m LSTM-Char-Large 19 m 78.9 KN-5 (Mikolov et al. 2012) RNN† (Mikolov et al. 2012) RNN-LDA† (Mikolov et al. 2012 genCNN<sup>†</sup> (Wang et al. 2015) 116.4 8 m FOFE-FNNLM† (Zhang et al. 2015) 108.0 6 m Deep RNN (Pascanu et al. 2013) 107.5 Sum-Prod Net<sup>†</sup> (Cheng et al. 2014) 100.0 LSTM-1<sup>†</sup> (Zaremba et al. 2014) 82.7 20 m LSTM-2<sup>†</sup> (Zaremba et al. 2014)

5-gram LM (not neural network)

Plain RNN for LM

Word-level LSTM

Table 3: Performance of our model versus other neural language models on the English Penn Treebank test set. PPL refers to per plexity (lower is better) and size refers to the approximate number of parameters in the model. KN-5 is a Kneser-Ney 5-gram language model which serves as a non-neural baseline. For these models the authors did not explicitly state the number of parameters, and hence sizes shown here are estimates based on our understanding of their papers or private correspondence with the respective authors.
